

Database II (420-416-AB)

Assignment #4 PHP And Oracle (6%)

Objectives:	To use PHP to create the front-end for our Recipes database.
Due Date:	As per Lea.
Late Policy:	Late submission accepted (up to max 3 days) 10% penalty per day.
Deliverables:	PHP files and any required HTML/CSS files. SQL file containing any view functions and stored procedures required.

You must create a PHP page to display a list of **categories** in your Recipes database. This must show the category name, description and total number of recipes in that category.

When users click on a category, they must be taken to another PHP page which displays a list of **recipes in the selected category**. You should choose fields which are relevant to display on this page. Use fields you think would help a user decide which recipe they might want to cook.

When users click on a recipe, they must be taken to another PHP page which displays all the **information for the selected recipe**. Include all the information stored in our database for that recipe, and an image (using the method discussed in class).

Create a **search feature** for your recipes database. Users must enter an **ingredient** and see a list of recipes that contain this ingredient. Use a HTML form and PHP to process the form data. Choose the fields which you feel are relevant to display on the search results page. Make sure that any recipe clicked on in the search results page must take the user to the recipe page created previously.

Create a **rating feature** for your recipes database. Users must be able to provide a review/rating for a recipe (You do not need to implement a login system – you can accept reviews/ratings from a user without finding out who they are).

You must have a **homepage** that makes use of the views you created in your previous assignment to display **quick recipes** (total cook time is an hour or less) and **easy recipes** (recipes with five ingredients or less). It should also display a **featured recipe** (chosen at random). This must be clickable so the user can view the recipe page for the featured recipe. You must also implement a **temperature conversion feature** and include it in your homepage.

All pages should be fully functional, contain **valid** PHP/HTML, and follow **good coding practices**. All variables must be bound to **prevent SQL injection**, and efficient use of **views**, **functions** and **stored procedures** must be included. Bonus marks will be given for effort into making the pages look **visually appealing** through the use of CSS. You can use a CSS framework (e.g. Bootstrap) if you wish to do so.
